Divide and Conquer

1. *Kleinberg, Jon. Algorithm Design (p. 248, q. 5)* Hidden surface removal is a problem in computer graphics where you identify objects that are completely hidden behind other objects, so that your renderer can skip over them. This is a common graphical optimization.

In a clean geometric version of the problem, you are given n non-vertical, infinitely long lines in a plane labeled $L_1 \dots L_n$. You may assume that no three lines ever meet at the same point. (See the figure for an example.) We call L_i “uppermost” at a given x coordinate x_0 if its y coordinate at x_0 is greater than that of all other lines. We call L_i “visible” if it is uppermost for at least one x coordinate.

Figure 5.10 An instance of hidden surface removal with five lines (labeled 1-5 in the figure). All the lines except for 2 are visible.

- (a) Give an algorithm that takes n lines as input and in $O(n \log n)$ time returns all the ones that are visible.

Solution:

- (b) Write the recurrence relation for your algorithm.

Solution:

- (c) Prove the correctness of your algorithm.

Solution:

2. In class, we considered a divide and conquer algorithm for finding the closest pair of points in a plane. Recall that this algorithm runs in $O(n \log n)$ time. Let's consider two variations on this problem:
- (a) First consider the problem of searching for the closest pair of points in 3-dimensional space. Show how you could extend the single plane closest pairs algorithm to find closest pairs in 3D space. Your solution should still achieve $O(n \log n)$ run time.

Solution:

- (b) Now consider the problem of searching for the closest pair of points on the surface of a sphere (distances measured by the shortest path across the surface). Explain how your algorithm from part a can be used to find the closest pair of points on the sphere as well.

Solution:

- (c) Finally, consider the problem of searching for the closest pair of points on the surface of a torus (the shape of a donut). A torus can be thought of taking a plane and “wrap” at the edges, so a point with y coordinate MAX is the same as the point with the same x coordinate and y coordinate MIN. Similarly, the left and right edges of the plane wrap around. Show how you could extend the single plane closest pairs algorithm to find closest pairs in this space.

Solution:

3. *Erickson, Jeff. Algorithms (p. 58, q. 25 d and e)* Prove that the following algorithm computes $\text{gcd}(x, y)$ the greatest common divisor of x and y , and show its worst-case running time.

```
BINARYGCD(x,y):  
  if x = y:  
    return x  
  else if x and y are both even:  
    return 2*BINARYGCD(x/2,y/2)  
  else if x is even:  
    return BINARYGCD(x/2,y)  
  else if y is even:  
    return BINARYGCD(x,y/2)  
  else if x > y:  
    return BINARYGCD( (x-y)/2,y )  
  else  
    return BINARYGCD( x, (y-x)/2 )
```

Solution:

4. Use recursion trees or unrolling to solve each of the following recurrences. Make sure to show your work, and do NOT use the master theorem.

- (a) Asymptotically solve the following recurrence for $A(n)$ for $n \geq 1$.

$$A(n) = A(n/6) + 1 \quad \text{with base case} \quad A(1) = 1$$

Solution:

- (b) Asymptotically solve the following recurrence for $B(n)$ for $n \geq 1$.

$$B(n) = B(n/6) + n \quad \text{with base case} \quad B(1) = 1$$

Solution:

- (c) Asymptotically solve the following recurrence for $C(n)$ for $n \geq 0$.

$$C(n) = C(n/6) + C(3n/5) + n \quad \text{with base case} \quad C(0) = 0$$

Solution:

- (d) Let $d > 3$ be some arbitrary constant. Then solve the following recurrence for $D(x)$ where $x \geq 0$.

$$D(x) = D\left(\frac{x}{d}\right) + D\left(\frac{(d-2)x}{d}\right) + x \quad \text{with base case} \quad D(0) = 0$$

Solution:

Coding Questions

5. Line Intersections:

Implement a solution in either C, C++, C#, Java, Python, or Rust to the following problem.

Suppose you are given two sets of n points, one set $\{p_1, p_2, \dots, p_n\}$ on the line $y = 0$ and the other set $\{q_1, q_2, \dots, q_n\}$ on the line $y = 1$. Create a set of n line segments by connecting each point p_i to the corresponding point q_i . Your goal is to develop an algorithm to determine how many pairs of these line segments intersect. Your algorithm should take the $2n$ points as input, and return the number of intersections. Using divide-and-conquer, your code needs to run in $O(n \log n)$ time.

Hint: How does this problem relate to counting inversions in a list?

Input should be read in from stdin. The first line will be the number of instances. For each instance, the first line will contain the number of pairs of points (n). The next n lines each contain the location x of a point q_i on the top line. Followed by the final n lines of the instance each containing the location x of the corresponding point p_i on the bottom line. For the example shown in Fig 1, the input is properly formatted in the first test case below.

Figure 1: An example for the line intersection problem where the answer is 4

Constraints:

- $1 \leq n \leq 10^6$
- For each point, its location x is a positive integer such that $1 \leq x \leq 10^6$
- No two points are placed at the same location on the top line, and no two points are placed at the same location on the bottom line.
- Note that the results of some of the test cases may not fit in a 32-bit integer.

Sample Test Cases:

input:

```
2
2
4
1
10
8
6
6
2
5
1
5
9
21
```

1
